ROADLINK

Business Process Explanation

1. Introduction

ROADLINK is a proposed Road Disruption Reporting and Transport Coordination System. Its purpose is to help road users report problems affecting roads and allow authorized transport officers to review and manage those reports.

The process connects drivers, the ROADLINK system, the database, transport officers, and other road users. It ensures that submitted information is checked before being shared as a verified road update.

2. How the Process Begins and Progresses

The process begins when a driver or road user opens the ROADLINK application. The user registers or logs into an account and submits a road problem by providing its location, category, and description.

After submission, the ROADLINK system receives the report and checks whether all required information has been provided. If information is missing, the system asks the driver to provide the missing details. If the report is complete, it is forwarded to the transport office for verification.

The transport officer reviews the report details and checks the available evidence and information. The officer then decides whether the report is verified. If it is not verified, the report is rejected. If it is verified, the officer approves it and may enter an alternative route when necessary.

The system records the report, verification decision, road status, and any alternative route in the database. It can also store notification records. Once the information is processed, other drivers and passengers can receive road updates, view verified road conditions, and check available alternative routes. This completes the process.

3. Roles of Each Actor

- **Driver/Road User:** Registers or logs in, submits road disruption reports, and provides the required location and incident details.
- **ROADLINK System:** Receives reports, checks required information, requests missing details, and forwards complete reports for verification.
- **Transport Officer:** Reviews reports, checks evidence, approves or rejects reports, and enters alternative routes when needed.
- **Database:** Stores user accounts, road reports, verification decisions, road statuses, alternative routes, and notification records.
- **Passengers and Other Drivers:** Receive Road updates, view verified road conditions, and check alternative routes before travelling.

4. Decision-Making and Information Flow

The process contains two main decisions.

First, the ROADLINK system checks whether a report is complete. If it is incomplete, the driver must provide the missing information. If it is complete, the report moves to the transport office.

Second, the transport officer decides whether the report is verified. A rejected report does not become an approved road update. An approved report is recorded, and an alternative route can be added if necessary.

Information moves from the driver to the system, from the system to the transport officer, and then to the database. After verification, the updated road information is made available to other road users. The solid arrows in the diagram represent the process sequence, while the dashed arrows represent data or information movement.

5. How the Process Supports Operations and Management

ROADLINK supports daily transport operations by organizing how road problems are reported, checked, approved, and shared. It helps officers manage incoming reports and gives road users access to verified road information.

The stored information can also support management decision-making. For example, transport officers can review report statuses, examine recorded disruptions, and use available information to decide where attention or alternative routes may be needed.

As the developer, I plan to use this process to guide the design of the database and application. It will help ensure that reports are properly managed, verification decisions are recorded, and useful road updates reach the people who need them.

As I conclude, the ROADLINK business process provides a clear connection between road users and transport officers. It starts with report submission, continues through information checking and officer verification, and ends with sharing approved road updates and alternative routes. This structured process is intended to improve road information sharing and support transport coordination.
